for their valuable insights and review throughout this project.

Executive Summary

Decarbonization of the electricity sector calls for a greater reliance on renewable energy sources including biomass for generating electricity. In 2023, approximately 54% of the total electricity generated in California came from renewable energy sources, 39% came from natural gas, and the remaining was obtained from nuclear power. Of the renewable energy sources, biomass fueled 2% of the state's total net generation with more than half of that coming from wood and wood-derived fuel (U.S. Energy Information Administration, 2023a). Woody biomass is unique in that it is one of the few renewable energy sources that can provide 24/7 baseload power. Wood-based biomass for energy reduces greenhouse gas emissions over traditional fossil fuels, generates income and employment opportunities in rural forest-dependent communities, provides the market outlet for unwanted materials, reduces the amount of garbage ending up in landfill sites, and has positive effects on forests' health if done sustainably.

This report provides an overview of electric power generation industries in California and estimates the economic contributions of wood-based biomass power generation industries on the state's economy. It is one of the multiple coordinated and comparable state reports produced across the country. The forest statistics information used in the report comes from the U.S. Forest Service's Forest Inventory and Analysis data, and the economic data come from the 2017 Impact Analysis for Planning (IMPLAN), a commercially available economic input-output (IO) model.

To help quantify the economic effects of the wood-based biomass power generation industry on California's economy, the economic contribution analysis was conducted using impact analysis for planning (IMPLAN), an input-output modeling software, and 2017 IMPLAN data using the Analysis-by-Parts (ABP) technique. IMPLAN does not have a separate sector to represent the wood-based biomass power generation industry and incorporates it as a part of electric power generation using the biomass sector (noted by IMPLAN sector 45 in cloud version of IMPLAN data). This sector also includes other sources of biomass such as agricultural byproducts, landfill gas, municipal solid waste, black liquor, and sludge waste. Hence, to

estimate the economic contributions resulting from only the wood-based biomass portion of the total mix, the ABP method was used. APB allows the user to create a customized industry sector by using the information about that sector's budgetary spending pattern and labor income. The supplementary data for conducting the economic contribution analysis was obtained from the mail survey of biomass power generation industries located in the 20-state Northeast Midwest study region conducted by the Michigan Department of Natural Resources in the Fall of 2022 and a review of the existing literature on wood-based biomass power generation in the U.S. The economic contribution estimates presented in this report are expressed in 2017 dollars.

The cost per MWh of electricity produced using wood and wood-derived fuel for California was obtained from the mail survey of biomass power plants located across the country including the twenty Northeast and Midwest U.S. states, along with California, Georgia and Virginia. It was estimated to be \$63/MWh. In California, the wood-based biomass power generation industry directly employed 154 people and generated \$187 million in direct output to the state's economy in 2017. Including ripple effects, the industry created a total of 1,694 jobs and contributed \$409 million in total output to the state's economy. In terms of tax contributions, the industry generated ~\$37 million at the state and local levels and ~\$34 million at the federal level in 2017. The social accounting matrix multipliers for the industry output was found to be 2.2. This means that for every 1 job in the wood-based biopower industry, an additional 10 jobs were supported in other sectors of the economy. Likewise, for \$1 million in output in the state's wood-based biopower industry, an additional \$1.2 million in output was supported in the rest of the economy. In terms of employment, the top three industries affected by the state's wood-based biomass power generation industry apart from itself included commercial logging, support activities for agriculture and forestry, and commercial and industrial machinery and equipment repair and maintenance industry.

Glossary

Biomass: Renewable organic material that comes from plants and animals. It contains stored chemical energy from the sun. Sources of biomass for energy include wood and wood processing waste, agricultural crops and waste materials, biogenic materials in municipal solid waste, animal manure, and human sewage.

Woody Biomass: It encompasses biomass obtained from the trees and woody plants, including limbs, tops, needles, leaves, and other woody parts, grown in a forest, woodland, or rangeland environment, that are the byproducts of forest management.

Biopower: Biopower technologies convert biomass fuels into heat and electricity. There are three main methods of releasing the energy stored in biomass to produce biopower: burning, bacterial decay, and conversion to gas/liquid fuel.

Net Electric Power Generation: Generation is a measure of electricity produced over time. Some portion of the electricity produced by the power plants is used internally to operate these plants. Net generation excludes electricity use for power plant operations.

Power Plant Capacity: It is the maximum level of electricity that a power plant can supply at a specific point in time under certain conditions.

Nameplate Capacity: Nameplate generator capacity is determined by the generator's manufacturer and indicates the maximum output of electricity a generator can produce without exceeding design thermal limits.

Kilowatt (kW): A standard unit for measuring electricity. 1 kW is equivalent to 1,000 Watts.

Kilowatt-hour (kWh): One kW of electricity generated or used for one hour.

Megawatt (MW): 1,000 kW

Megawatt hour (MWh): 1,000 kWh

Economic Contribution Terms

Direct effects/contributions: The economic activities (e.g., output, employment, labor income, and value-added) associated with an industry or sector in the study area. These can describe the current economic sectors or changes in those sectors.

Employment: The number of full- and part-time jobs associated with an industry plus self-employed individual.

Indirect effects/contributions: The impact of local industries purchasing goods and services from other industries, leading to others' outputs, employment, and labor income.

Induced effects/contributions: The impact of labor income (employee compensation and proprietor income) via goods and services purchased due to direct and indirect spending by industries.

Labor income: The dollar total of employee compensation and proprietor income; the latter is associated with self-employed individuals.

Output: The dollar measure of production within an area; it is also viewed as sales.

Type I multiplier: These multipliers are derived by dividing the sum of direct and indirect effects by the direct effects.

Social Accounting Matrix (SAM) multipliers: These multipliers are derived by dividing the sum of direct, indirect, and induced effects by the direct effects. The social accounts include payments made between households, households, and government and more. These are available for output, employment, labor income, and value-added and are used to assess the effects of changes in industry activity (i.e., “ripple effects”).

Total effects/contributions: The sum of direct, indirect, and induced effects.

Value-added (also known as gross state product, or GSP): The sum of labor income, other property income (e.g., rents and profits), and indirect business taxes (e.g., excise and sales taxes). It is the difference between an industry’s total output and the cost of its intermediate inputs. The sum of value-added for all economic sectors within the state equals the total GSP.

Introduction

There is a growing interest in generating a greater share of electric power using renewable energy sources in the United States. This interest stems from increasing concerns over the negative environmental, human health, and economic effects of continued reliance on non-renewable fossil fuels for energy. Further, the emphasis on renewable electricity generation is important for ensuring energy security and for creating opportunities for local and rural development.

The U.S. electricity consumption has risen over the years reaching a total of 4.07 trillion kilowatt hours in 2022 (US Energy Information Administration (EIA) 2023b) and the short-term forecast is for increasing energy consumption owing to demands from new semiconductor and battery manufacturing factories as well as data centers (US EIA 2025). To keep up with the increasing demand, the U.S. electricity generation has also increased substantially over the years. In 2023, the U.S. generated a total of 4.17 trillion kilowatt hours of electricity (US EIA 2023c). The U.S. electric power industry accounted for approximately 33% of the total U.S. energy-related CO₂ emissions in 2022 (US EIA 2023d). This is because most of the electricity produced in the country (60%) comes from fossil fuel sources such as coal, natural gas, and petroleum (US EIA 2023c). Approximately 19% of the electricity produced in 2023 was generated using nuclear energy and 21% using renewable energy sources (US EIA 2023c). Despite making considerable progress in transitioning to clean energy over the last two decades, the U.S. electricity sector still accounts for about a quarter of the U.S. climate pollution (Center for American Progress, 2023). Approximately 356 billion kilowatt hours of electricity were produced using renewable energy sources in the U.S. in 2000. By 2022, the amount of electricity produced using renewable energy sources increased to reach over 900 billion kilowatt hours (US EIA 2023e). This is an impressive increment. Nonetheless, for improved environmental outcomes associated with the electric power generation industry in the future, a greater share of electricity production in the country needs to come from renewable energy sources.

Over the years, state and local governments have played a pivotal role in promoting the use of renewable energy sources for producing electricity. This has been done through the

implementation of focused sectoral strategies and incorporation of performance standards along with supporting policies (Center for American Progress, 2023). As of December 2023, 28 U.S. states along with the District of Columbia have established a renewable portfolio standard (RPS), seven states have set renewable portfolio goals, and eleven states have clean energy standards or goals identified moving forward (U.S. EIA 2023f). These can be requirements or goals for energy producers and providers to supply energy from low- or zero carbon emission sources (U.S. EIA 2023f).

In California, approximately 54% of the total electricity generated in 2023 came from renewable energy sources, mostly solar (US EIA 2023a). Biomass contributed about 2% of the state's net electricity generation the same year with wood and wood-derived fuel contributing three-fifth of it (US EIA 2023a). Biomass is an important source of renewable energy that is used for facility heating, electric power generation, and combined heat and power generation. It includes a variety of materials, including wood and wood processing wastes, agricultural crops and waste materials, biogenic materials in municipal solid waste as well as animal manure and human sewage (US EIA 2023g). Biomass can be converted into electric power and heat through several different methods, the most common being direct combustion. Other methods include gasification, pyrolysis, and anaerobic digestion (US EIA 2023g). One of the primary benefits of using biomass for power generation is that it can provide baseload or firm power, unlike other renewable energy sources such as solar and wind (Bracmort 2016).

The utilization of woody biomass for power generation offers numerous societal, economic, and environmental benefits. Wood-based biomass for energy reduces greenhouse gas emissions over traditional fossil fuels, generates income and employment opportunities in rural forest-dependent communities, reduces the amount of garbage ending up in landfill sites, and has positive effects on forests' health if extraction is done following sustainability standards (National renewable energy laboratory 2023, Gan and Smith 2007). Substantial volumes of woody biomass are removed annually by private, state, and federal forestland managers in the process of managing forests to protect it against wildfires, insects, diseases, and invasive species. Additionally, woody biomass can also result from natural disasters such as hurricanes and tornadoes as well as urban cleanup activities (USDA Forests and Rangelands 2025). Most of

the materials resulting from these management activities can decay or be burned in place or hauled to landfills in the absence of market outlet such as biomass power generation (USDA Forests and Rangelands 2025). Biomass power generation, therefore, offers an important avenue for the disposal of woody biomass, thus contributing to improving air quality, visibility, and public health by reducing the smoke created by burning woody biomass. It also helps to offset the high costs of forest management activities, hazardous fuel treatment operations, restoration activities, and post-harvest cleanup operations by providing an economic value to nonmerchantable and low value wood (Page-Dumroese et al. 2022). Biomass power generation thus indirectly contributes to reducing wildfires and helps to preserve wildlife habitat and watersheds while creating economic opportunities for the communities (USDA Forests and Rangelands 2023). Additionally, when manufacturers of wood products make products such as lumber, furniture, pallets, and paper, they generate substantial amounts of residues that can be underutilized in absence of markets for such products. Less than 50% of the tree that is harvested ends up in the final product leaving a large volume of residues that can be used for energy generation (Abbuelh et al. 2004).

Since biomass-based electricity production requires a high initial investment and the facilities are likely to use local feedstock for energy production compared to electricity generation using fossil fuel sources, they are likely to have greater impacts on local income (Faaij et al. 1998). Besides, power generated from woody biomass, if managed sustainably, may qualify as carbon neutral, since CO₂ released during power generation is displacing CO₂ emissions from fossil fuels and can be sequestered through the production of additional trees (International Energy Agency 2022). However, to be considered truly carbon neutral, a full supply chain including all emissions associated with production, processing, transportation, and the use of biomass for energy production needs to be considered (International Energy Agency 2022).

Despite its benefits, electricity generation from woody biomass in the U.S. has remained relatively stable over the past two decades, with a slight decline in recent years (Figure 1). In California, woody biomass contributed about 1.7% of the total electricity produced in the state in 2000. In 2023, it contributed about 1.3% of the total electricity produced in the state (US EIA

2023h). Nationally, there were a total of 247 biopower facilities using wood and wood-derived fuels across the country in 2017 (US EIA 2023i). Out of these, 25 were located in California (Figure 2).

Figure 1. U.S. electricity generation from biomass, 2001 to 2022. (Source: U.S. Energy Information Administration 2023i).

Figure 2. Map depicting the locations of biomass power plants using wood and wood-derived fuels in California in 2017 (Source: U.S. Energy Information Administration 2023i).

Estimating the economic contributions of wood-based biomass power generation industry in a region can help emphasize the ripple effects of this industry to the regional economy and help to advocate for its sustenance and expansion in the future. Realizing this, in 2022, Michigan Department of Natural Resources (MI DNR) Forest Resources Division contracted with a research team at Michigan State University, Department of Forestry along with its collaborators (from North Carolina State University, Oklahoma State University, University of Idaho, SUNY College of Environmental Sciences and Forestry, and the Michigan Biopower) to conduct the economic contribution analysis of wood-based biomass power generation industry to the regional economy of the twenty-state Northeast and Midwest U.S. states along with California, Georgia and Virginia for calendar years 2017 and 2022 respectively.

As a part of this project, a 2017 regional report highlighting the economic contributions of wood-based biomass power generation industry to the regional economy of the Northeast and Midwest U.S. states has been developed. Accompanying this regional report, are individual state reports for fourteen participating states summarizing the economic contributions of wood-based biomass power generation industry to the respective state's economy. Fourteen participating states include California, Connecticut, Georgia, Illinois, Maine, Massachusetts, Michigan, Minnesota, New Hampshire, New York, Pennsylvania, Vermont, Virginia, and Wisconsin. This report is one of the individual state reports developed for the state of California. Its purpose is to summarize the economic contributions of wood-based biomass power generation industry to California's economy.

The next sections of the report shed light on the status of electric power generation industry in California; briefly discuss the condition of forest resources within the state; outline the methods employed for conducting the economic contribution analysis of wood-based biomass power-generating industries in California; and discuss the findings obtained from the analysis.

Electric power generation in California in 2017

In 2017, the electric power industry in California produced a total of ~206 million Megawatt hours of electricity. Natural gas was the major source of electricity generated across the state followed by conventional hydroelectric power and solar energy respectively (Figure 3). Out of the total electricity generated, approximately 1% or 2.9 million Megawatt hours were produced using wood and wood-derived fuel (Figure 3) (US EIA 2023i).

Figure 3. Percentage of total electricity generated in California in 2017 by energy source (Source: U.S. Energy Information Administration 2023i).

Collectively the electric power generation industry employed 22,531 people in CA in 2017 which is equivalent to 0.10% of total jobs in the state the same year (IMPLAN 2017). The direct economic effects resulting from various power-generating industries within the state including biomass are listed in Table 1.

Table 1. The direct economic effects of power generating industries in California based on 2017 IMPLAN data.

IMPLAN Sector Code	Energy Source	Employment	Labor Income	Value-Added	Output
(Electric Power Generation)			(Millions of 2017 dollars)		
39	Hydroelectric	1,592	465	1,088	1,676
40	Fossil fuel	9,073	2,042	8,016	15,429
41	Nuclear	3,341	773	2,194	3,893
42	Solar	902	324	465	683
43	Wind	1,059	424	1,691	2,571
44	Geothermal	786	167	350	595
45	Biomass	720	324	485	875
46	All other	783	239	140	315
47	Electric power transmission and distribution	4,275	875	2,776	6,468
	Total electric power generation, transmission and distribution	22,531	5,634	17,206	32,504
	Total All Sectors	23,658,261	1,682,190	2,799,945	4,565,858

Forest Resources of California

Forestlands cover approximately 30% of the total land area in California (USDA Forest Service, Forest Inventory and Analysis 2025). Out of this, ~52% of the forestlands can produce commercial timber and are identified as timberlands. Most of the forests in the state (57%) are under federal ownership, followed by private (39%), and the state and local government (4%) respectively (Figure 4). Western oak and California mixed conifers are the major forest types in the state followed by Ponderosa pine forest types (Table 2).

Figure 4. Forest ownership in California (Data source: Sass et al. 2020).

Table 2. Forestland area in California by forest type (Source: USDA Forest Service, Forest Inventory and Analysis 2025).

Forest Type Group	Acres	Percentage
Western oak group	9,025,055	29%
California mixed conifer group	7,618,455	24%
Ponderosa pine group	2,298,322	7%
Other western softwoods group	2,016,490	6%
Fir/spruce/mountain hemlock group	1,946,928	6%
Tanoak / laurel group	1,786,918	6%
Pinyon / juniper group	1,471,469	5%
Douglas-fir group	1,189,495	4%
Lodgepole pine group	926,887	3%
Redwood group	822,923	3%
Other	2,468,065	8%
Total	31,571,007	100%

The merchantable bole volume of live trees on timberlands in California are estimated to be 67.0 billion cubic feet (Table 3). The average annual net growth is 732 million cubic feet, annual removals are 551 million cubic feet, and annual mortality is 726 million cubic feet. Annual net growth of merchantable bole volume of growing stock trees in the timberlands exceeded the removals by a ratio of 1.3, meaning that for each cubic foot of timber harvested in the region, about 1.3 cubic feet of timber grew in the timberlands. However, this ratio varies by ownership type (Table 3). Across the state, the annual removals are close to 1% of the standing volume and annual mortality in the timberlands are much higher than annual removals (Table 3).

Table 3. Characteristics of state growing stock in California in 2025 (million cubic feet) (Source: USDA Forest Service, Forest Inventory and Analysis 2025).

Ownership	Net Volume	Annual Net Growth	Annual Removals	Annual Mortality	Growth/Removals
National Forest	36,926	87	192	556	0.5
Other federal	779	12	22	7	0.5
State and local	1,178	22	9	2	2.4
Private	28,164	611	328	160	1.9
Total	67,048	732	551	726	1.3

Methods

The analysis was conducted using impact analysis for planning (IMPLAN) software and 2017 IMPLAN data (online version) using the Analysis-by-Parts (ABP) technique. The ABP technique was chosen because it allows the user to create a customized industry sector by using the information about that sector's budgetary spending pattern and labor income (Lucas 2022). So far IMPLAN does not have a separate sector to represent wood-based biomass power generation. Instead, it is incorporated as a part of the electric power generation using the biomass industry. This means that it includes power generation from all sources of biomass including agricultural byproducts, landfill gas, municipal solid waste, woody biomass, black liquor, and sludge waste. To separate the economic contributions associated with wood-based power generation from power generation using all forms of biomass, the analysis-by-parts (ABP) technique was used. The resulting economic contributions are measured in terms of full- and part-time employment, industry output, value-added, labor income, other property income, and business taxes.

The information about industry spending patterns for the biomass power generation industry using woody biomass was obtained from Dahal et al. (2020) and corroborated or supplemented (where applicable) with the information collected through the mail survey of biomass power generation plants located in the twenty state Northeast-Midwest region along with California, Georgia and Virginia. In fall 2022, Michigan Department of Natural Resources conducted a mail survey of 120 biomass power industries located in the 20-state Northeast-Midwest region along with California, Georgia, and Virginia to collect the financial and resources utilization data for the year 2017. Overall, 11 responses were obtained (9.2% response rate), out of which nine responses were from the Northeast-Midwest region. The data obtained from these responses were used to inform and supplement the industry spending pattern for wood-based biomass power generation industries for regional and state level reports for participating states. The average operation and maintenance expenditure for the wood-based biomass power generation industry used for the economic contribution analysis is listed in Table 4.

The survey also asked respondents to indicate the total amount of electricity produced in 2017 using wood and wood-derived fuel along with the total cost of production. This information was used to estimate the cost per megawatt hour of electricity produced. It was estimated to be \$63/MWh on average when weighed by the size of production. The details of the survey method along with the information collected are included in the twenty-state Northeast-Midwest biopower economic contribution analysis report.

The per unit cost of electricity produced using wood and wood-derived fuel was multiplied by the total electricity produced using wood and wood-derived fuel within a state to obtain the direct output from the wood-based biomass power-generating industry in that state.

Information about the total electricity produced by the electric power generation industry using wood and wood-derived fuels in 2017 was obtained from US EIA (2023i). In California, ~2.9 million Megawatt hours of electricity were generated using wood and wood-derived fuel in 2017. At the rate of \$63/MWh of electricity produced, this translated into a direct output of \$186.9 million for the wood-based biomass power generation industry in the state. The direct output was then allocated into intermediate inputs and value-added following the percentage breakdown of output into its component parts for IMPLAN sector 45 (electricity generation using biopower industry) using 2017 IMPLAN data for California. According to it, approximately 44.5% of the output of the biomass power generation industry was comprised of intermediate inputs and 55.5% was value-added. Value added was further broken down into employee compensation (5.4%), proprietor income (31.7%), other property type income (6.8%), and taxes on production and imports (11.5%) following IMPLAN sector 45's percentage breakdown for California in the cloud version of IMPLAN data. Direct employment in wood-based biomass power generation industry was estimated using total output data and output per employee information obtained from IMPLAN 2017 model for California. Based on this, we estimated direct employment in wood-based biomass power generation industry in CA to be 154 in 2017.

When estimating the economic contribution of the biomass power generation industry in IMPLAN using the ABP technique, the local purchase percentage (LPP) for all other items in the industry spending pattern except woody biomass, was set to default SAM value. For woody

biomass, LPP was set to 100%. This is because all wood used by the biomass power generation industry is sourced locally as per the findings obtained from the mail survey (within 60 miles radius). Since it is not possible to precisely identify the location of production, transport, and purchase of other items included in the industry spending pattern for the wood-based biomass power generation industry, LPP was set to default SAM values for those items. Like Dahal et al. (2020), we estimated total taxes (including emission fee) to be 1.85% of total operation and maintenance cost, which amounted to \$3.4 million. This was modeled separately, and the resulting indirect and induced effects obtained from tax contributions were added to the total economic contribution summary for the state.

Table 4. Average operation and maintenance expenditures in 2017 US\$ for the wood-based biomass power generating industry (as per Dahal et al. 2020 and supplemented with information collected from a mail survey of the wood-based power generating industry in the Northeast and Midwest U.S. states along with California, Georgia and Virginia).

IMPLAN Sector	Cost category (sector)	MM US\$ per year	%
16	Biomass	7.94	58.6%
20	Natural Gas	0.01	0.05%
39	Utilities	0.38	2.8%
49	Water	0.22	1.6%
60	Building expenses	0.06	0.4%
154	Oil and diesel	0.11	0.8%
162	Chemical	0.17	1.3%
167	Supplies (consumable, urea, ammonia)	0.26	1.9%
384	Office supplies and expenses	0.03	0.2%
408	Gasoline (retail)	0.02	0.1%
433	Communication	0.03	0.2%
444	Insurance	0.21	1.6%
453	Equipment rental	0.01	0.1%
457	Outside support services (water treatment, vendor services)	0.08	0.6%
462	Consulting fees	0.05	0.4%
470	Office administrative service	0.14	1.0%
474	Travel and entertainment	0.02	0.1%
476	Janitorial	0.04	0.3%
479	Ash freight and waste management	0.4	3.0%
512	Vehicle repair	0.02	0.1%
515	Maintenance	0.98	7.2%
50001	Employee compensation	2.12	15.6%
	Total taxes (including emission fee)	0.25	1.8%
			100.0
	Total operation and maintenance cost	13.55	%

Results

The results obtained from the economic contribution analysis indicated that in California, the wood-based biomass power generation industry directly employed 154 individuals in 2017 with a labor income of \$69 million, value-added of \$104million, and output or sales of \$187 million in 2017 US dollars (Table 5). Including ripple effects, the industry supported a total of 1,694 jobs with \$168 million in labor income. The industry contributed a total of \$245 million in value-added and \$409 million in total output to the economy of California (Table 5). The top three industries affected in terms of output by wood-based biomass power generation industry in the state include biomass power generation industry itself, commercial logging (IMPLAN sector 16), and forestry, forest products and timber tract production industry (IMPLAN sector 15). In terms of employment, commercial logging, electric power generation using biomass industry and support activities for forestry and logging were affected the most (Table 6).

SAM multipliers for employment, labor income, value-added, and output were estimated to be 11.0, 2.4, 2.4, and 2.2 respectively. Output multiplier of 2.2 means that every \$1 million in output in the region's wood-based biopower industry supported an additional \$1.2 million in output to the rest of the economy. The relatively high employment multiplier compared to output, labor income, and value-added multipliers, reflect the biomass power industry's supply chain and spending patterns. It reflects the wood-based biomass power sector's dependence on labor-intensive upstream industries, especially commercial logging and forestry support services. These industries generate many jobs per dollar of spending, but with relatively modest wages and value added per worker. Additional induced effects in service industries further increase job counts. Consequently, employment multipliers are substantially higher than output, labor income, or value-added multipliers. It should be noted that IMPLAN employment is jobs including part-time, seasonal workers and proprietors head count, hence sectors that add lots of part-time, low-hour service jobs tend to increase the employment count though labor income and output remain modest.

The industry also contributed approximately \$34 million in federal and \$37 million in annual state and local taxes in 2017 (Table 7).

Table 5. Economic contributions of wood-based biomass power generation industry in California in 2017 US dollars using IMPLAN software and 2017 IMPLAN data.

Economic Contributions of Wood-based Biomass Power Generation Industry					
States Included		Employment	Labor Income	Value-added	Output
		(Jobs)	(\$MM 2017)		
California	Direct	154	69	104	187
	Indirect	859	60	69	106
	Induced	680	39	72	116
	Total Contribution	1,694	168	245	409
	SAM Multiplier	11.0	2.4	2.4	2.2

Table 6. The top five industries affected in terms of employment by wood-based biomass power generation industry in California in 2017

		Impact			Total
		Direct	Indirect	Induced	
1	Commercial logging (16)	0	512	0	512

Table 7. Total tax contributions of wood-based biomass power generation industry in California in 2017 US dollars (\$MM) using 2017 IMPLAN data.

Impact Type	Sub-county general	Sub-county special districts	County	State	Federal	Total
Direct	\$4.42	\$4.88	\$2.86	\$11.15	\$13.05	\$36.35
Indirect	\$0.77	\$0.86	\$0.50	\$3.85	\$11.85	\$17.82
Induced	\$1.29	\$1.43	\$0.84	\$4.25	\$8.99	\$16.80
Total	\$6.48	\$7.17	\$4.19	\$19.25	\$33.89	\$70.98

Summary

This study assessed the economic contributions of wood-based biomass power generation industry in California using IMPLAN, an input-output analysis software and 2017 IMPLAN data. It provides a snapshot of the economic effects of wood-based biomass power generation industry in terms of employment generated, value-added contributed and output produced using analysis by parts technique. The ABP technique was used to separate the economic contributions of wood-based biomass power generation from the contributions of biomass power generation in general, which also includes biomass sources other than wood and wood-derived fuel. The wood-based biomass power generation industry in California was found to directly support 154 jobs and contribute \$187 million in output to the state's economy. Including direct, indirect, and induced effects, the industry contributed a total of 1,694 jobs and \$409 million in output in California.
