NYS Forest Carbon Assessment

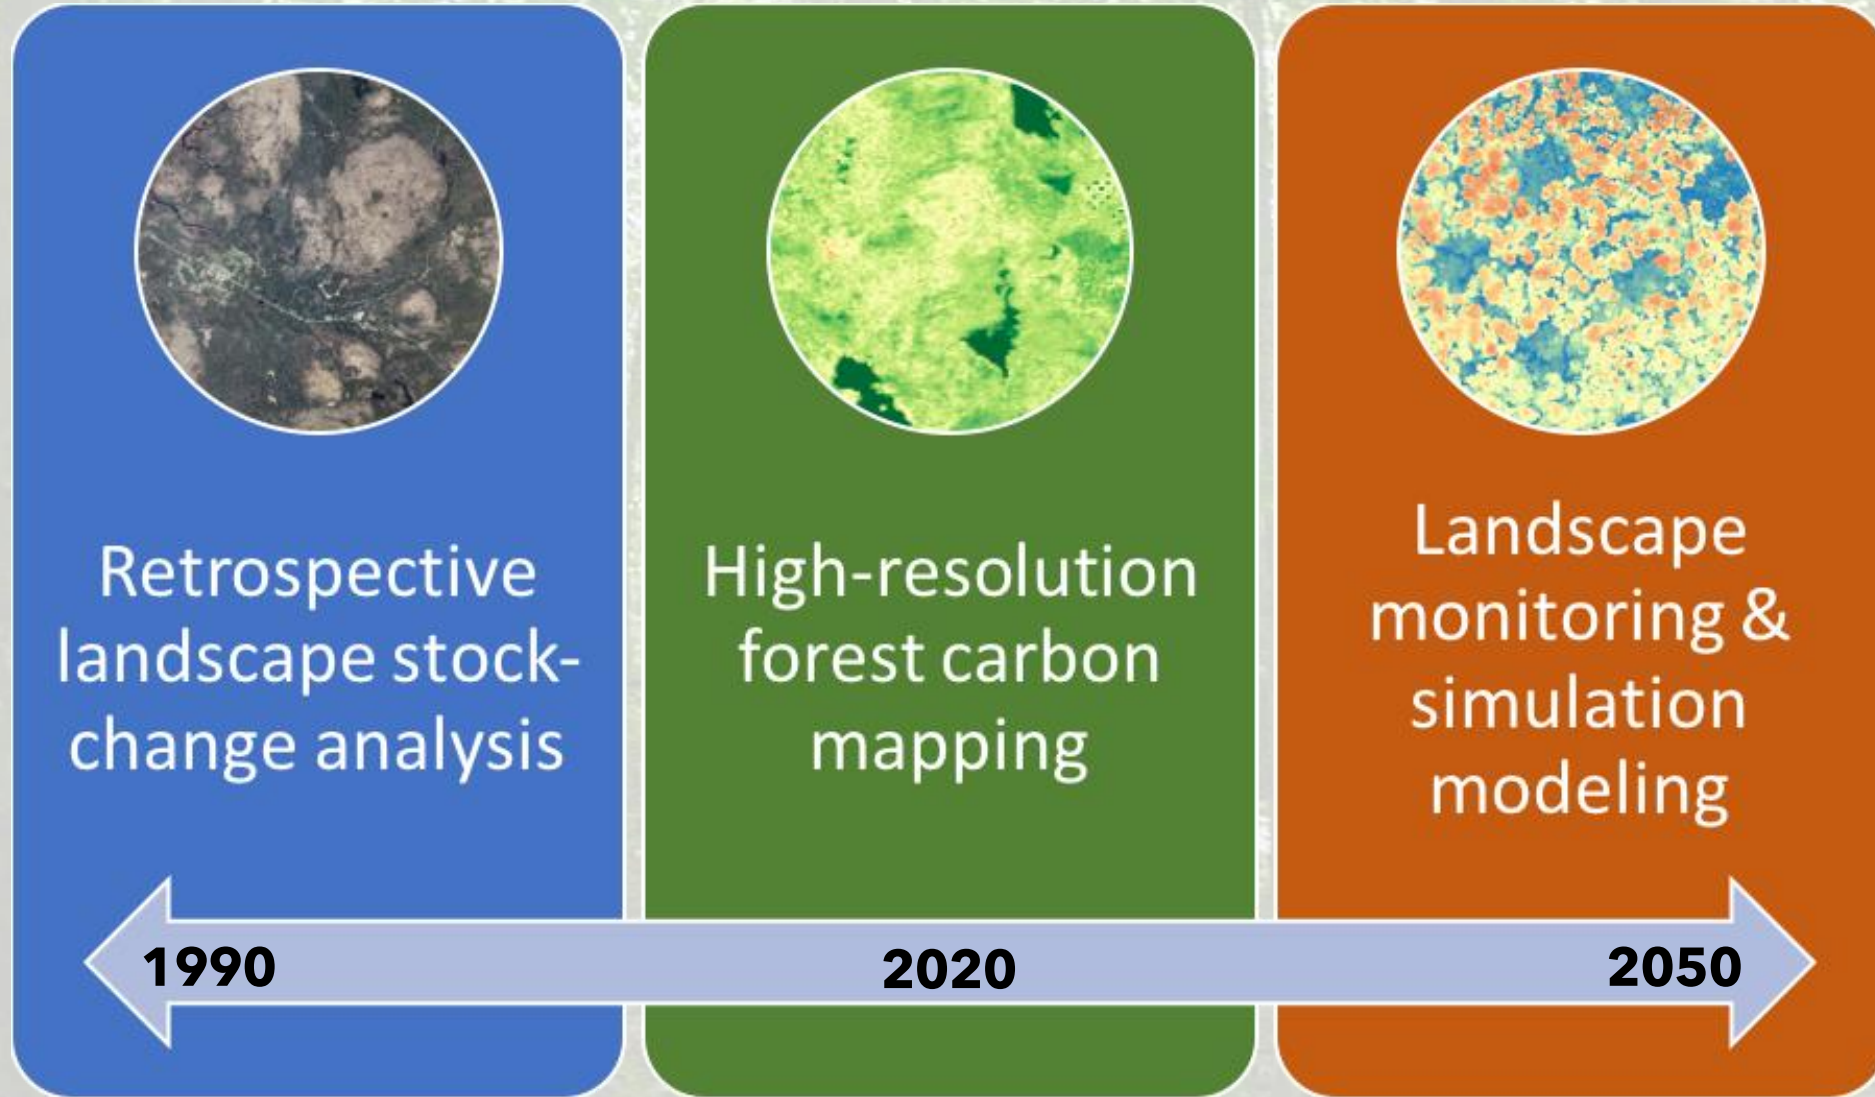

Goal: To develop a map-based carbon accounting system for ‘natural and working lands’ across New York State, to support policy and regulatory decisions, enhance monitoring/reporting/verification (MRV) capabilities, and inform forest stewardship practices

US Forest Service FIA reports state-level estimates of annual forest C stocks and changes (sequestration, emissions) to the EPA, based on statistical analysis of their field plot network (over 4,400 plots across NYS)

State-level stocks and trends are useful, but offer little actionable information at decision-relevant scales or insights on why, where, or how the forest C sink may be changing. So we set out to:

- Develop a statewide map-based inventory of forest biomass and carbon stocks
- Model and map retrospective (historical) forest biomass, carbon stocks and land use/land cover
- Apply historical forest maps/data in a stock-change framework to estimate sequestration and emissions
- Build a framework to observe future C stock-changes to support monitoring/reporting/ verification (MRV)

CAFRI is mapping **current** forest biomass & C stocks, estimating **recent patterns of changes** in C stocks, and monitoring **future patterns** in biomass and carbon, for all of New York state

Statewide annual 30m maps of forest biomass & carbon

(based on LCMAP)

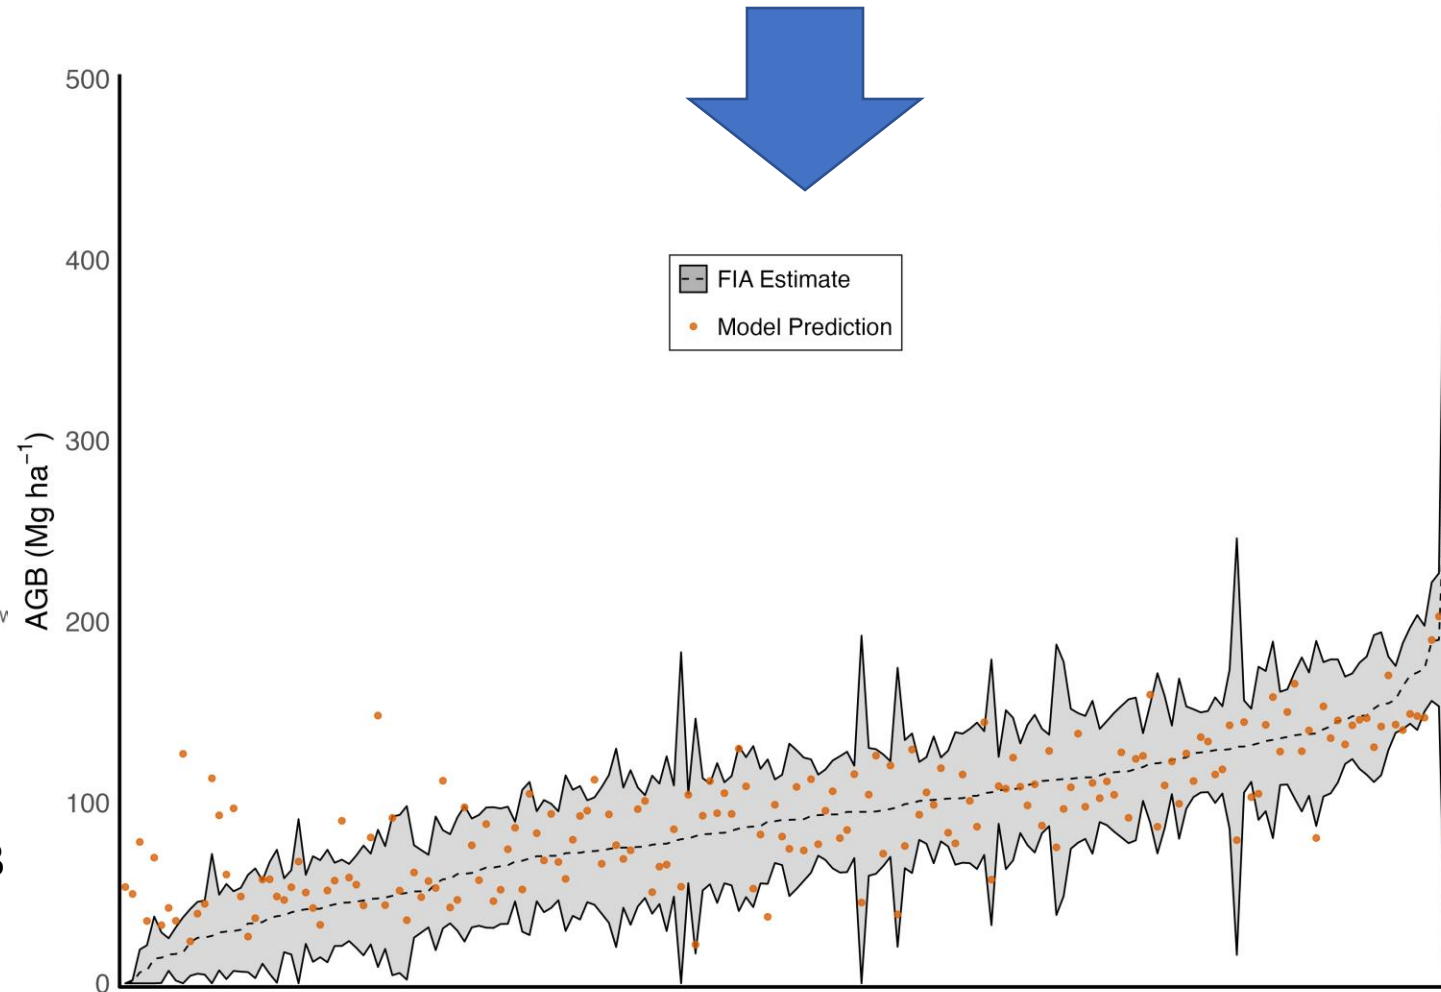

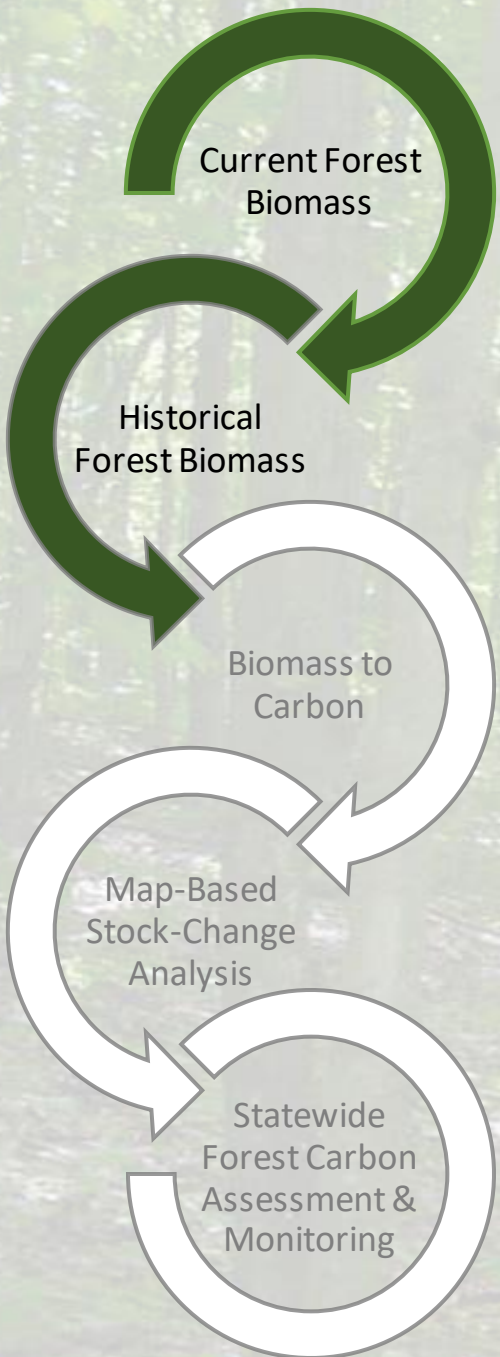

Map agreement with FIA small-area estimates

We compared our maps to FIA estimates of AGB for 'small-area' hexagons, which incorporate corrections for land cover (Menlove & Healey 2021)

We found that 89% of our AGB map predictions agreed with FIA design-based estimates, falling within their 95% confidence intervals for small area hexagonal estimates.

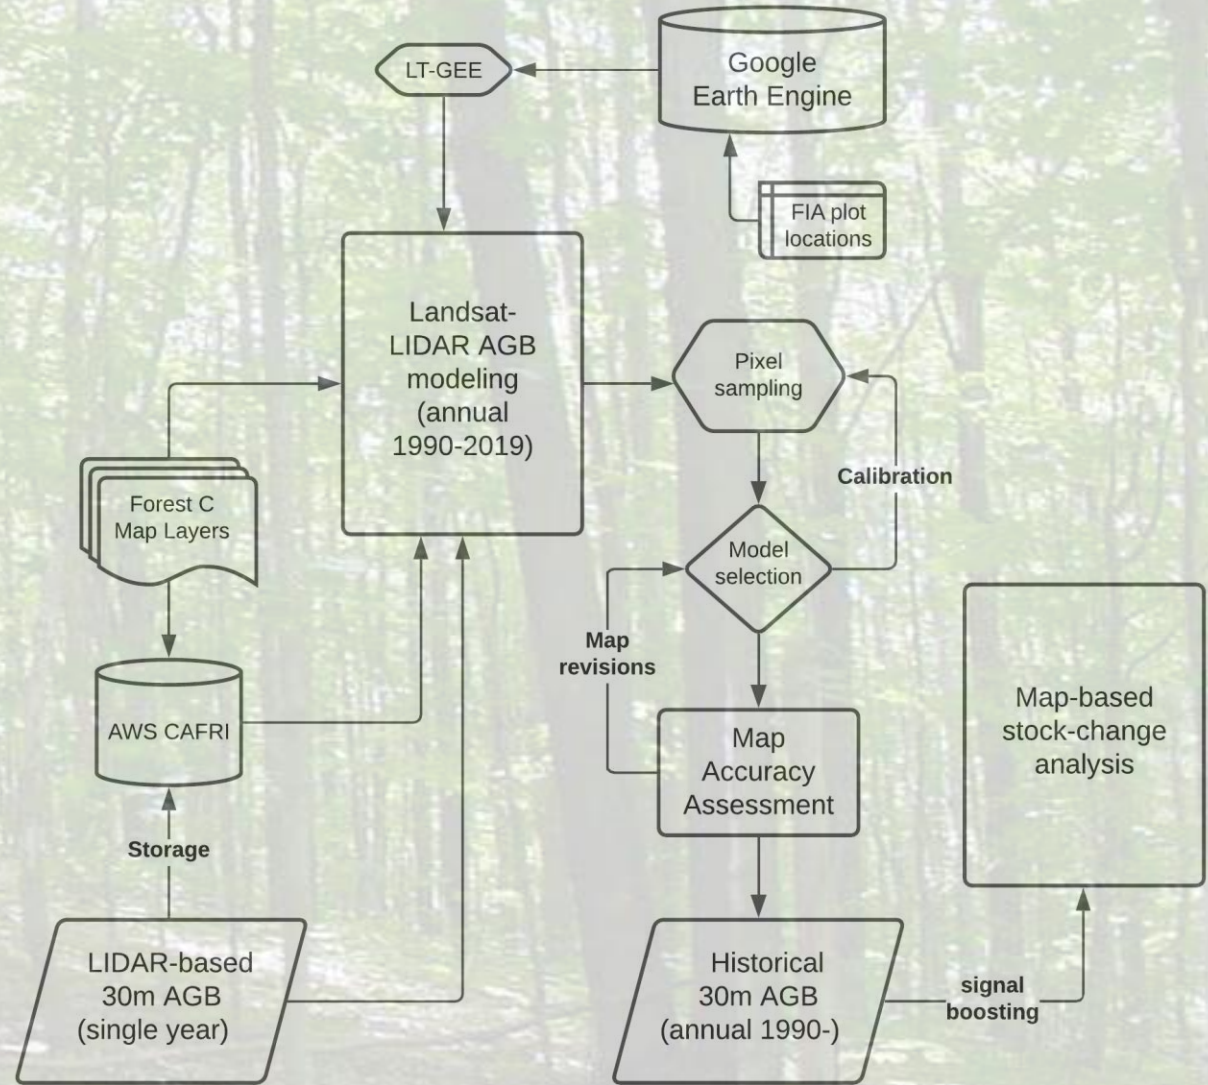

Use LIDAR-based maps of biomass (AGB) to train a second set of AGB models based on Landsat imagery

Use models and historical Landsat imagery to produce annual 30m AGB maps from 1990-2019

Evaluate the agreement between map predictions and FIA estimates at multiple scales

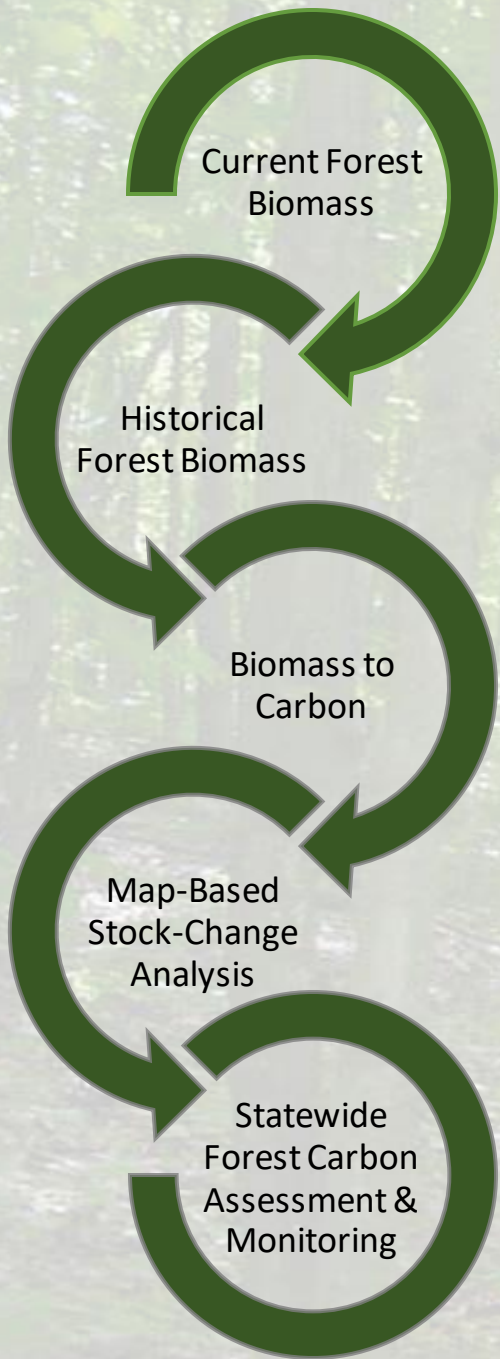

Mapping net carbon removals (sequestration) and additions (emissions)

Aboveground vegetation C stock-change maps track closely with biomass (AGB) maps and show areas of net sequestration (green) and emissions (orange) that align with known parcels and land use history

Soil C stock-change maps consistently show declines that are likely due to model error and uncertainty. Our models do not represent the processes by which soil C pools would decrease over time in reserved forests.

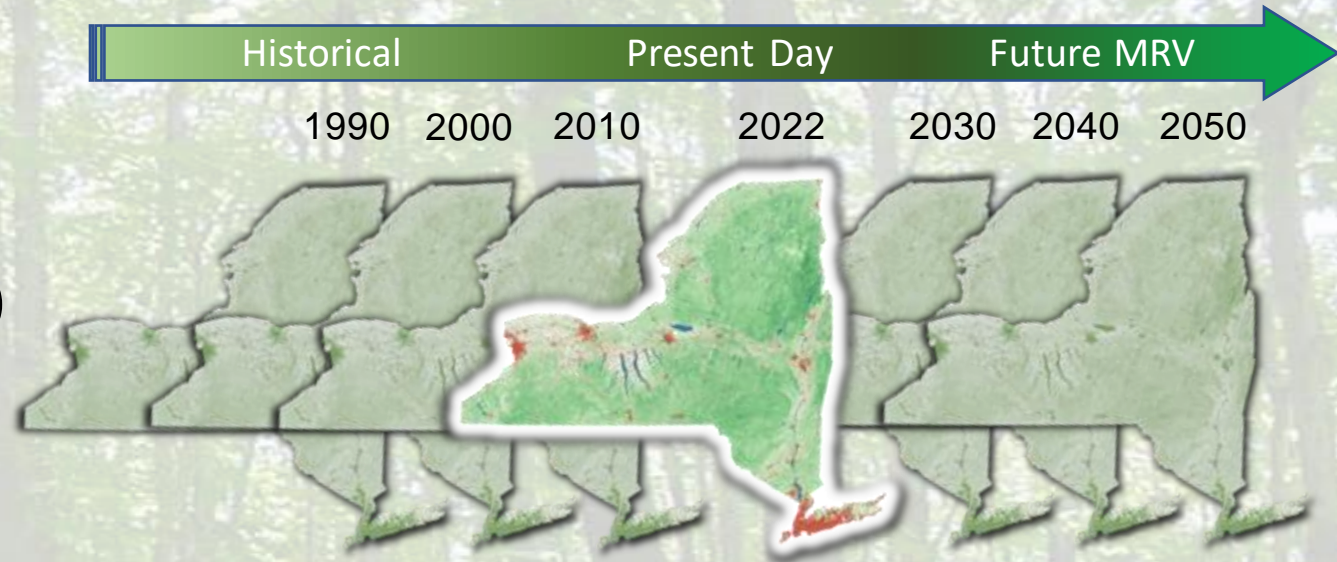

Build a system for statewide carbon monitoring, reporting and verification (MRV)

- Accuracy
- Cost-Efficiency
- Versatility

Version 1.0 based only on Landsat, FIA and suite of open-source data & tools
